

What is claimed is:

1. A system for addressing a data storage unit used in  
at least one of server and client computers, which  
5 comprises:

means for converting an external bus into an  
internal bus for use in the system;

a memory module for storing data on the internal  
bus therein, the memory module being divided into a  
10 plurality of equally-sized memory blocks; and

means for processing writing data on the internal  
bus in the memory module and reading out the data  
therefrom.

15 2. The system of claim 1, wherein the internal bus is  
a PCI (Peripheral Component Interconnect Bus) interface  
bus

3. The system of claim 1, wherein the converting means  
20 includes a SCSI (Small Computer System Interface)  
interface bus.

4. The system of claim 1, wherein the memory module is  
composed of any one of SDRAM(Synchronous Dynamic Random  
25 Access Memory), rambus DRAM(Dynamic Random Access  
Memory), DDR(Double Data Rate) or other equivalent  
memories.

5. The system of claim 1, wherein each of the plurality of equally-sized memory blocks is divided into a predetermined number of equally-sized sub-memories.

5

6. The system of claim 1, wherein the predetermined number is four.

7. The system of claim 5, wherein the memory module  
10 employs a tree hierarchical configuration, which again compensates signals at an intermediate stage and forwards it to a lower hierarchy.

8. The system of claim 7, wherein the memory module  
15 includes a PCI to memory controller of a tree hierarchical configuration, which is disposed between the internal bus and the plurality of sub-memories as a bridge, for controlling access to the plurality of sub-memories, which are distributed in a hierarchical  
20 fashion.

9. The system of claim 8, wherein the tree hierarchical configuration is designed to allow a clock delay to be compensated at the PCI to memory controller.

25

10. The system of claim 4, wherein the PCI to memory controller activates any of the plurality of sub-

memories to be actually accessed and maintains the remaining in a low power mode.

11. The system of claim 10, wherein the PCI to memory  
5 controller includes a register block having a lower  
address bit, an upper address bit and a select bit,  
wherein the lower address bit represents an address of a  
set region within a memory map, which is in the range of  
the address region, the upper address bit is set when a  
10 memory address region from which the memory map is  
departed is used, and the select bit is used to directly  
access the memory module.
